

Temporal Diversification Weekly Playbook

Flyxion

2026

1 Goal

Sustain engagement by managing a portfolio of unfinished histories on different clocks, not by demanding continuous novelty from a single process.

2 Weekly Portfolio Construction

Maintain at least four active scopes:

- **Fast** ($\tau \approx$ minutes–hours): daily execution and immediate feedback.
- **Medium** ($\tau \approx$ days): experiments and short deliverables.
- **Slow** ($\tau \approx$ weeks): proofs, architecture shifts, chapter drafts.
- **Very slow** ($\tau \approx$ months+): foundational programs and long manuscripts.

3 Operational Rules

1. **Never require all scopes to POP weekly.** Long horizons stay unresolved by design.
2. **Require anti-starvation updates.** Every slow scope must receive at least one structural event per week.
3. **Default action under local flattening: BIND.** If immediate closure is premature, add a constraint that sharpens next continuation.
4. **Use REFUSE to cut dead branches quickly.** Remove known-nonproductive continuations.
5. **Use COLLAPSE to reduce bookkeeping overhead.** Merge distinctions no longer decision-relevant.

4 Daily Scope-Selection Procedure

At each work block:

1. Estimate candidate gains for active scopes: $\max_{a \in O_i} \text{EMCG}_i(a \mid F_t)$.
2. If a slow scope is near starvation threshold, prioritize it.

3. Otherwise choose action by highest gain-per-cost.
4. Log the event type (POP/REFUSE/BIND/COLLAPSE) and whether saturation or recovery was observed.

5 Weekly Review Metrics

Track:

- time-to-local-saturation (per scope),
- total time in field saturation,
- recovery latency after switching scopes,
- starvation rate for slow scopes,
- stability of compression progress across horizons.

6 Applied Templates

Personal Workflow

One fast execution scope, one medium experimentation scope, one slow integration scope, one very-slow thesis scope. Weekly requirement: no slow scope receives zero events.

Education

Design schedules that interleave immediate drills, multi-day projects, and long-form inquiry. Measure whether boredom events correlate with local flattening in only one horizon.

Research and Programming

Treat deep projects as unresolved scopes; require periodic BIND-like refinement events (lemma sketch, boundary condition, interface constraint) even without POP.

AI Agent Orchestration

Use multi-clock schedulers where long-horizon tasks get explicit anti-starvation allocations instead of purely greedy short-horizon optimization.
